

IUT Laundry cleans the clothes of almost 1400 students per week, which is a difficult job to do. They usually collect dirty clothes from South Hall on Mondays and North Hall on Fridays. As the student number has increase drastically, they have decided not to come to the halls to collect the clothes. Instead, from now onwards, the students have to go to the laundry to submit for or collect their clothes from cleaning. As a prominent database engineer, you are given the task to build the system for the laundry. Follow the specifications while building the system which are given below:

1. Create a table ***cloth_owner_info*** which would contain the important informations of the students who are submitting their clothes to the laundry. It will contain the following attributes - **entry number**, **name of the student**, **his/her student id**, **number of clothes** and **date of submission**. As the entry number would be large and sequential, the manager cannot remember it. So, create a method so that the manager does not have to give input of the entry number, the program automatically determines it.
2. The laundry is supposed to return the clothes in 7 days. So if any student comes to submit his/her clothes after 7 days, you have to make sure that his/her previous submissions are already collected/delivered. If not, give a warning message to the manager and do not take the new clothes. However, if he/she comes within 7 days, the laundry should combine the previous order with the new order and delete the previous order. The date should be adjusted accordingly. You can use as many tables as you want to implement this feature.
